PREFACE

The extremely long missions of the two Viking Orbiter spacecraft have produced a wealth of photos of surface features. Many of these photos can be used to form stereo images allowing the earth-bound student of Mars to examine his subject in 3-D. This catalog is a technical guide to the use of stereo coverage within the complex Viking imaging data set. Since that data set is still growing (January, 1980, about 3½ years after the mission began), a second edition of this catalog is already planned. Completion is expected about November, 1980.

INTRODUCTION

Spacecraft Imaging Data

Remote evaluation of the surface geology of extraterrestrial objects consists, in large part, of studies of television images using techniques developed by terrestrial aerial photogeologists. Of course, unlike terrestrial geologists, the planetary geologist often has little or no additional data from other forms of remote sensing or surface samples to guide his studies. For this reason it is extremely important that the investigator understand the nature of his imaging data - its full potential and its weaknesses. For instance, as compared to a typical conventional aerial photograph of the earth, most planetary images contain far less information, but that information is strictly numerical in its original form, most often a digital magnetic record, and so may be subject to quantitative photometric analysis.

Stereo data on relief of surface features seen in overlapping images is another type of information that has often gone unexploited by planetary geologists. Qualitative and quantitative evaluation of landscape morphology and stratigraphic and structural relationships are all considerably aided by access to three dimensional imaging. This is particularly true for terrains without recognized terrestrial analogues.

The planet Mars has a great variety of puzzling geologic features and a general complexity of structure and stratigraphy second only to the Earth. This catalog is intended to facilitate access to stereo imaging data for investigators of Martian geology.

Viking Orbiter Imaging Data

Since the two Viking orbiters arrived at Mars in the summer of 1976, approximately 50,000 images have been acquired. The standard format of Viking orbiter frames recorded as photographs is shown in Figure 1-1. The picture label contains considerable information on lighting and viewing conditions, including almost everything needed to recognize stereo pairs and orient them for viewing. Two types of photographic renditions were made from the Viking images, the original perspective view from the camera focal plane and a version transformed by computer to a map projection. These versions may be identified by the words "rectilinear" and "orthographic," respectively, in the top center label. Computer codes were also used to selectively enhance image features. The standard enhancements

SCO= IMAGE SCALE (M/PIXEL) ORTHO
VERSION

most often applied to Viking images were: (1) a linear contrast enhancement to rectilinear versions and (2) a filter to remove low spatial frequencies followed by a linear contrast enhancement to orthographic versions. A simple linear transformation of grey level information is recognized by the code "SCR" appearing in the top center label. Any of several spatial filtering algorithms is recognized by the code "NGF."

The Viking pictures are made up of a regular array of grey dots (pixels). Tic marks around the edge of the image indicate the pixel scale - 100 pixels between major tic marks (Fig. 1-1). Orthographic projections also have a scale bar next to the image. Those scale bars labeled "KM" can be used confidently; others may be in error. At the upper right hand corner is the "PICNO," a picture ID unique to an image. It is a combination of orbit number, spacecraft ID, and frame number for that particular orbit. At the lower right is a roll and frame ID unique to one version of an image recorded on 5-inch film. A given digital image with a unique PICNO may have been recorded on film in several versions, each with a different roll/frame ID.

Camera ID number, filter color, and exposure are recorded at the lower left (Fig. 1-1). Immediately to the right is a data block containing the location and size of the area imaged and the lighting and viewing conditions at the time. Image scale and orientation parameters refer to the rectilinear format. The individual parameters are defined in Figure 1-1. At the bottom center is a graphic display of the digital manipulation of the image grey level content which preceded recording on film. Other data in the picture label are less relevant to the problem of stereo viewing, and so are not described here.

Because of initial Viking Project goals, operations constraints, the varied desires of experimenters for the several orbiter instruments, and the limited durations of commitments to extend the Mission, the imaging record of the Viking Orbiters has many characteristics of an artist's collage. We have thousands of fractional views of Mars at different seasons and under different lighting and viewing conditions. Fortunately these views overlap geographically, so it is possible to find at least one image of any place on the planet. In a few areas the Viking images may not be of sufficient quality to entirely supplant the use of earlier high resolution Mariner 9 images (1), but, typically, the Viking Orbiters acquired the highest quality imaging of surface features. In addition, for surprisingly large areas, overlapping images constitute a valuable source of stereo topographic data.

Not surprisingly, useful stereo imaging cannot be easily located by going through a Viking Project index which lists pictures by geographical location (2). Images suitable for viewing under a stereoscope or for compilation into topographic maps must, aside from being targeted to the same location, be somewhat similar in atmospheric clarity conditions, lighting conditions, spatial resolution, and contrast of surface features.

Cataloging Procedures and Criteria

In assembling this catalog we have attempted to screen out large amounts of data unsuitable for stereo analysis, identify similar overlapping images, and then evaluate quantitatively their coverage and stereo viewing characteristics. We have eliminated from consideration large numbers of images showing dense cloud cover, images for which less than 70% of the data was successfully recorded, images for which the viewing perspective (EMA) was greater than 65° from the zenith, and images for which the solar illumination (INA) was greater than 85° from the zenith.

Overlapping images taken from differing perspectives were then grouped according to spatial resolution so as to ensure comparison of images differing up to 50% in resolution. These images were then screened to eliminate combinations for which solar azimuth differed by greater than 45° , solar incidence by greater than 30° , or for which differences in the distribution of surface (polar) ice would make the scene appearances very dissimilar.

Except for most evaluation of cloud cover, comparisons of images were made through the SEDR (Supplementary Experiment Data Record) (3). These engineering data are admittedly imperfect, but our experience indicates that the data being used are sufficiently precise for a practical stereo catalog. The only major exception is some of the highest resolution coverage with defective SEDR data. These images were mostly screened out of this edition of the catalog, but will be fully evaluated for the next edition.

For each area of stereo coverage identified, a record was made of spatial resolution, the image ID's (PICNO's) involved, the location of the area, and the viewing conditions. Calculations were then performed to determine the strength of the stereo viewing geometry and the optimum orientation of the pictures under a stereoscope for discriminating relief differences.

Catalog Organization

All this information is presented to the catalog user through maps of locations of stereo coverage (Section 4) and indexed tables listing images and stereo viewing data (Section 2). In addition, we have provided a supplementary list of lighting and viewing data and a roll/frame order number for each image in the catalog (Section 3). Because orthographic map projection and filtering commonly facilitate stereo viewing, the frame order number refers to an ORTHO/NGF version of the image when one is available. It is expected that the normal pattern of use for this catalog will be that a feature of known latitude and longitude is the subject of study. The investigator will consult the appropriate index map to determine whether stereo coverage has been identified for that location. If it has, the corresponding table will show the characteristics of that coverage and provide a list of photographs for study. Characteristics of individual photos and order numbers will be found in the supplementary data list.

The maps of stereo data set coverage (Section 4) are compiled according to a few simple conventions. Except for polar regions beyond 80° latitude, each map covers an area of Mars measuring 10 degrees latitude by 10 degrees longitude. The areas are numbered from the north to south and east to west around each 10° tier of latitude (Figure 1-2). The area ID number and the specific latitude - longitude limits of each map are shown below the map. For rectangular maps, north is toward the top. Within a map different line symbols outline areas covered by specific sets of stereo images. The index number of the stereo set is located inside the outlined area as close to the upper left corner as practical. As necessary to clarify map relationships, the area index number has also been placed on top of the corresponding line symbol.

Because the sliver shape of the extreme polar (80° to 90° latitude) $10^{\circ} \times 10^{\circ}$ regions would result in a very inconvenient set of index maps, the regions have been consolidated into "quads" measuring 10° latitude by 90° longitude. In the north polar region, for example, Quad 1 is the area from 80° to 90° N and 0° to 90° W.

The listings of stereo data sets (Section 3) are ordered and numbered in the same way as the index maps. The column headings are defined:

M = map index number of stereo data set

Fig. 1-2

10

DEGREE

BOXES

Rb = range bin. The stereo sets are grouped according to spatial resolution into seven intervals of range:

<u>Rb</u>	<u>Slant Range</u>	<u>Resolution (m/pixel)</u>
1	<1000km	<25
2	800-1600km	20-40
3	1200-2400km	30-60
4	1800-3600km	45-90
5	2700-5400km	67.5-135
6	4100-8200km	102.5-205
7	6200-12400km	155-310

These range bins were chosen to insure that stereo pairs differing by up to 50% in resolution would be considered for the catalog.

Stereo Set 1, Stereo Set 2 = the PICNO ID's of the photographs covering the designated map area

T = target, approximate center coordinates (latitude longitude) of the area of stereo coverage

S1,S2 = approximate subspacecraft coordinates (latitude, longitude) during acquisition of pictures of Stereo Sets 1 and 2, respectively

Em1,Em2 = approximate spacecraft zenith angles (EMA in picture label) at target for Stereo Sets 1 and 2, respectively

V = angular separation in azimuth on Mars of locations S1 and S2 measured at T. This is also the angle between the two spacecraft directions (S/CAZ in picture label) for a stereo pair of orthographically projected images aligned for viewing (Fig. 1-3)

W1,W2 = orientations of spacecraft directions, relative to the eye-eye line, for optimum viewing of relief in an overlapping picture pair from Stereo Sets 1 and 2 (Fig. 1-3)

BLANK PAGE

BLANK PAGE

FIGURE 1-3 OPTIMUM STEREO VIEWING GEOMETRY

PICTURES ORIENTED AS SHOWN BELOW UNDER A STEREOSCOPE WILL PROVIDE
OPTIMUM DISCRIMINATION OF ELEVATION DIFFERENCES.

- Fe = the projection of the parallax angle, or Em1 and Em2, into a vertical plane parallel to the eye-eye line with photos oriented for optimum viewing of relief differences (see W1, W2 above)
- Left = set number of the pictures which should be placed to the left under a stereoscope, observing the convention to set up oblique views from a forward looking and upright perspective

Stereo coverage in range bin 7 for the extreme polar region (80° - 90° latitude) was omitted from the quad maps in this edition of the catalog to improve legibility. That coverage will be shown in a second edition of this catalog, now in preparation. Stereo coverage at lower resolution for the entire planet will also be included in that updated catalog.

Figure 1-3 illustrates the use of the angles W1 and W2 and Left set number to align a picture pair for viewing. The procedure for setting up a pair is as follows. Pick out from the stereo sets two pictures with substantial overlap, one from Stereo Set 1 and one from Stereo Set 2. From the table determine which set is the Left Set and place the picture from that set in the left viewing position. From the picture label or the SEDR data listing (Section 3) determine S/CAZ, the spacecraft direction, for each picture. Orient the two pictures so the spacecraft directions diverge from the eye-eye line by angles W1 and W2, as shown in Figure 1-3. To bring the images into coincidence, forming a three dimensional image should now require only translation and slight rotation of one picture.

It is necessary that the two images be of identical scale to form a stereo image. This can be accomplished by printing the pictures to identical scale, as through use of the scale bars on orthographically projected versions. Alternatively a sliding-wing-mirror stereoscope can be employed. Movement of the mirrors allows some adjustment of relative image size.

Acknowledgements

Compilation of this catalog has been supported at the Planetary Science Institute by the Viking Project under JPL contract 954149 and by the NASA Planetary Geology Program under contract NASW 3208.
